

# DENSITY AND BUOYANCY

**Density and Buoyancy**

**Reading Passage**

Read the passage carefully before answering the questions that follow.

Density is a measure of how much mass is contained within a substance. In comparison, buoyancy is an object's tendency to float or sink in a fluid. Buoyancy is often measured by comparing an object's density with that of the fluid it is in. Objects with a density less than that of the fluid will float, while objects with a density greater than that of the fluid will sink.

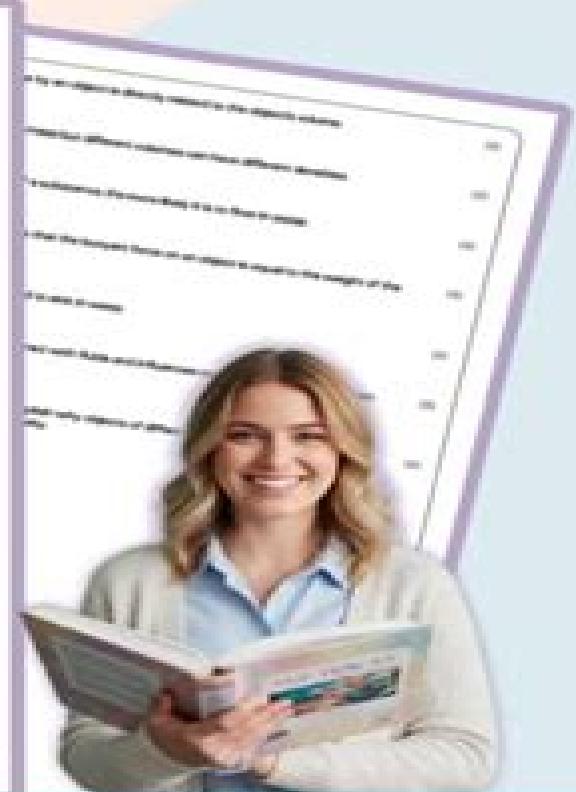

The concept of density is often applied to liquids as well. Liquids are often denser than air, which is why they can hold more mass. When liquids are heated, they expand, which causes them to become less dense. This is why hot liquids are less dense than cold liquids, as well as why liquids are less dense than gases.

Properties of water are also important for many natural processes. For instance, ice floats on water because it has a lower density than liquid water. This allows aquatic life to survive in cold areas. Having water in its cells, cells in water, increases its water density, causing it to contract and become denser. As a result, water is denser than ice, which is why ice floats on top of water. This is why icebergs are able to float on the surface of the ocean.

**True or False: Density and Buoyancy Concepts**

Circle either true or false in front of each statement.

1. An object with a higher density than water will sink when placed in water.
2. A buoyant float has enough mass to float in water to support objects having a mass of 1000 kg.
3. An object with a density less than that of water will float.
4. Ice floats on water because it has a lower density than liquid water.
5. Objects with less volume, regular shape and irregular shape have buoyancy force.
