

Activity 10.1

Reading material on our website on genetic variation in gametes complements each of the following questions. Read carefully and understanding of the concepts discussed will be tested.

1. Match each of the following changes in chromosome structure to its definition:

☒ A. Crossing

☐ B. Duplication

☐ C. Inversion

☐ D. Translocation

1a. a section of a chromosome is inserted

1b. a piece of a chromosome is deleted

1c. a segment of one chromosome has moved elsewhere; different, non-homologous, chromosomes

1d. a section of a chromosome appears twice or more times in a row

2. How many genetically different gametes can be produced from a diploid cell with seven chromosomes pairs? Explain your answer.

Answer: The number of genetically distinct gametes that can be produced is equal to 2^n , where n is total number chromosomes pairs. A diploid cell with seven chromosomes has a total number of 2^7 or 128 genetically distinct gametes.

3. Although you will learn a mechanism of mutation from your reading, you recognize that some traits are the less frequent occurrences. For example, both color and eye color. Why may some traits be inherited together?

These traits are inherited together and travel on the same chromosome. This is how they are passed down together, and a mutation may only occur once affecting both traits. Chromosome mutations from traits will be found on the same chromosome in the gametes, usually inherited together with the linked trait.

4. Describe the alignment of chromosomes during prophase I, write the equation:

Homologous I homologous pairs and homologous chromosomes align together, called synapsis. This is important because it allows the crossing over to occur and results in the genetic recombination.

5. How does recombination lead to chromosomal polymorphism number? Describe two types of genetic mutations that can result from recombination.
