Natural Methane Emissions in a Changing Arctic - Implications for Climate and Environment Karin Andreassen, Jochen Knies, Susanne Liebner, Andrew Jonathan Hodson, Carolyn Ruppel, 2024-11-06 Natural emissions of methane have received much attention over the last decade due to the documented increase of methane in the atmosphere and high global warming potential relative to CO<sub>2</sub>. Over the past few decades the Arctic has been warming approximately four times faster than the rest of the planet driving a pressing need to assess the current and future vulnerability of various natural methane sources. In the Arctic vast amounts of methane are stored in soils and permafrost or are being generated as permafrost thaw continues. Additionally there are large stores of methane in Arctic gas hydrates, a solid form of concentrated methane and water and in numerous settings including deep water marine areas on continental shelves hosting relict subsea permafrost and gas hydrate in and beneath onshore permafrost and likely beneath the Greenland Ice Sheet. Continued climate warming is making methane leakage more likely. Even deeper conventional gas reservoirs could leak methane as the overlying permafrost degrades.

Ruminants are hooved mammals with a unique digestive system that allows them to better create energy from fibrous plant material than other herbivores. Small ruminants such as sheep and goats play an important role in global food security and nutrition as well as in the livelihoods of farmers and others along the food chain. Due to the unique digestive systems of ruminants, many major studies have focused on the effects of high concentrate diets on rumen fermentation, ruminal acidosis, and their microbial properties and functions. Therefore, paying attention to the intestinal health of small ruminants during the rapid fattening stage has important implications for their health and productivity. Ruminants host a taxonomically diverse microbiota in their rumen which is generally considered to be the most efficient natural fermentation system. Rumen microorganisms facilitate the degradation of otherwise indigestible plant fibres into absorbable compounds such as proteins and volatile fatty acids, the main source of energy and nutrition for ruminants. They are composed of a complex and dynamic assembly of bacteria, fungi, archaea, protozoa, and viruses. Diets and additives directly affect the number and viability of rumen microorganisms.
