

POGIL - Gene Expression: Transcription

How is mRNA synthesized and what message does it carry?

Why?

DNA is often referred to as a genetic blueprint. In the same way that blueprints contain the instructions for construction of a building, the DNA found inside the nuclei of cells contains the instructions for assembling a living organism. The DNA blueprint carries its instructions in the form of genes. In most cases the genes direct the production of a polypeptide, from which other more complex proteins, such as enzymes or hormones, may be constructed. These polypeptides and other molecules run the organism's metabolism and, in multicellular

organisms, dictate what each cell's job is. So, what is the language of these instructions and how are they read and decoded by the cellular organelles? This activity will focus on the decoding of genes in eukaryotes.

Model 1 - Transcription

4. Refer to Model 1.

- What is the base-pair rule for a DNA strand matching an RNA strand?
- Compare this base-pair rule with that of two DNA strands.

5. Which strand of the DNA contains the "blueprint" for the pre-mRNA?

6. Consider Model 1.

- In which direction is the DNA molecule read? _____
- The DNA strand and pre-mRNA strand are anti-parallel. With this in mind label the 3' and 5' ends of the pre-mRNA strand in Model 1.
- In which direction is the pre-mRNA molecule constructed? _____

7. Before printing presses were available, books had to be transcribed in order to share the information.

- 1. Consider the eukaryotic cell in Model 1.**
 - a. Where in the cell is the DNA found?
 - b. Where in the cell does transcription take place?
- 2. Refer to Model 1.**
 - a. What polymer is synthesized during transcription?
 - b. What monomers are used to construct this polymer and where are they found?
- 3. According to Model 1, what enzyme is required for transcription? (Hint: Think about how enzymes are named. What ending is used for enzyme names?)**

Host-Pathogen Interactions During Arboviral Infections Alan G. Goodman, Angela L. Rasmussen, 2019-07-19. Arboviruses or arthropod borne viruses such as West Nile virus, Dengue virus and Zika virus pose a serious threat to public health worldwide. West Nile virus was introduced to the United States in 1999 and is now endemic, causing over 2 000 domestically acquired cases in the U.S. annually in mammals. Similarly, dengue and Zika viruses are endemic in the Americas and pose novel threats to the human population. Tick borne viruses such as Powassan virus and Heartland virus are increasing in frequency in the U.S. At this time, there is no commercially available vaccine or therapeutic to treat these viral infections. Because nearly every mammalian case of these virus infections originates from the insect vector, it is imperative that we also understand viral pathogenesis, transmission and the immune response in insect models as well as pathogenesis and the host responses in infected mammals. The development of methods to block arbovirus transmission from the vector may be effective at ceasing arthropod to human infection since the current recommendation to prevent these viral infections is to decrease contact with mosquitoes. Additionally, improving our understanding of epidemiology and ecology will also help.

develop measures to reduce virus spread In order to better study mammalian and insect host responses to infection a number of genetic tools are available such as fly mosquito and tick models recombinant viruses mouse models and bioinformatics tools The studies described in this eBook will illustrate host responses to infection using mammalian and insect models identify critical signaling nodes of the innate immune response and discuss virus transmission from insect to mammal or among infected hosts Taken together these studies will elucidate means of decreasing infections in human populations and provide potential targets for future study and therapeutic design Journal of Experimental Biology ,2003 Plant Molecular Biology D.
