transponders An RFID tag is a small object that can be attached to or incorporated into a product animal or person An RFID tag contains an antenna to enable it to receive and respond to Radio Frequency RF queries from an RFID reader or interrogator Passive tags require no internal power source whereas active tags require a power source As of today 2006 the concepts of ubiquitous computing and ambient intelligence are becoming widespread In order for these to become a reality a number of key technologies are required In brief these technologies need to be sensitive responsive interconnected contextualised transparent and intelligent RFID and in particular passive RFID tags are such a technology In order to deliver the necessary characteristics that could lead to ambient intelligence however there are some challenges that need to be addressed Remote powering of the tags is probably the most important challenge Issues concerning the antenna tag interface and the rectifier design that allow the RF signal to be converted to Direct Current DC are top priorities Secondly the communication link and the reader should be optimized The RF signal that contains the tag data suffers from a power of four decay with the distance between tag and reader As a result both the reader sensitivity and the tag backscattered power efficiency have to be maximized Long range powering as well as sufficient communication quality are the guidelines of this work This work proposes a linear two port model for an N stage modified Greinacher full wave rectifier It predicts the overall conversion efficiency at low power levels where the diodes are operating near their threshold voltage The output electrical behavior of the rectifier is calculated as a function of the received power and the antenna parameters Moreover the two port parameter values are computed for particular input voltages and output currents for the complete N stage rectifier circuit using only the measured I V and C V characteristics of a single diode Also presented in this work is an experimental procedure to measure how the impedance modulation at the tag side affects the signal at the reader The method allows the tag designer to efficiently predict the effect of a modulator design at the system level and gives a useful instrument to choose the most appropriate impedances Finally the design of a fully integrated remotely powered and addressable RFID tag working at 2.45GHz is described The achieved operating range at a 4W Effective Isotropically Radiated Power EIRP reader transmit power is at most 12 m The Integrated Circuit IC is implemented in a 0.5 um silicon on sapphire technology A state of the art rectifier design is embedded to supply energy to the transponder Inductive matching and a folded dipole antenna are key elements for achieving this performance
