Heat generated by combustion of particulates in the heater induces combustion of particulates within the DPF. A control module selectively enables current flow to the electrical heater for an initial period of a DPF regeneration cycle and limits exhaust flow while the electrical heater is heating to a predetermined soot combustion temperature.

**Advanced Direct Injection Combustion Engine Technologies and Development** H Zhao, 2009-12-18 Volume 2 of the two volume set *Advanced direct injection combustion engine technologies and development* investigates diesel DI combustion engines which despite their commercial success are facing ever more stringent emission legislation worldwide. Direct injection diesel engines are generally more efficient and cleaner than indirect injection engines and as fuel prices continue to rise DI engines are expected to gain in popularity for automotive applications. Two exclusive sections examine light duty and heavy duty diesel engines. Fuel injection systems and after treatment systems for DI diesel engines are discussed. The final section addresses exhaust emission control strategies including combustion diagnostics and modelling drawing on reputable diesel combustion system research and development. Investigates how HSDI and DI engines can meet ever more stringent emission legislation. Examines technologies for both light duty and heavy duty diesel engines. Discusses exhaust emission control strategies, combustion diagnostics and modelling.

**Modeling and Analysis of Particulate Matter Deposition and Regeneration in a Diesel Particulate Filter** Mengting Yu, 2013 Diesel engines are widely used because of their high efficiency and low greenhouse gas emission. The particulate matter (PM) emitted by a diesel engine is collected and then burned in a diesel particulate filter (DPF). Analysis and modeling works have been done in this research to provide insight on optimization of the DPF design and operating conditions to achieve low pressure drop across the filter to decrease fuel consumption and low peak temperature during regeneration to avoid filter melting, cracking and/or catalyst deactivation. Limiting models of the 1-D two channel DPF model are analyzed. Analytical predictions and physical insight on the filtration velocity, pressure drop, heat transfer, light off and regeneration in a DPF are obtained. The hydraulic analysis enables an efficient optimization of the DPF that leads to a more uniform PM deposition profile and a decrease of the pressure drop. The heat transfer, light off and regeneration analysis enable estimations of the DPF heat up time, the speed and width of the temperature front, the light off temperature and time and the peak regeneration temperature. New DPF regeneration procedures are proposed to limit the maximum local temperature rise. In various cases a DPF is connected by a wide angled cone diffuser to the engine exhaust pipe. A 2-D axisymmetric PM deposition and regeneration

model is developed to investigate the impact of the inlet cone on the deposition rate and the regeneration temperature as well as on the transient inlet velocity distribution among the various DPF channels. The highest regeneration temperature and thermal stress when using an inlet cone may be quite higher than when it is absent. A major technological challenge in the regeneration of the ceramic cordierite filter is that a sudden decrease of the engine load referred to as Drop to Idle (DTI) may create a transient temperature peak much higher than under either the initial or final stationary feed conditions. This excessive transient temperature rise may cause local melting or cracking of the ceramic filter. Suggestions on how to limit the peak temperature rise following a DTI are provided through numerous simulations of the 1-D and 2-D DPF regeneration models.

**Loading and Regeneration Analysis of a Diesel Particulate Filter with a Radio Frequency-Based Sensor**, 2010. Accurate knowledge of diesel particulate filter (DPF) loading is critical for robust and efficient operation of the combined engine exhaust aftertreatment system. Furthermore, upcoming on-board diagnostics regulations require on-board technologies to evaluate the status of the DPF. This work describes the application of radio frequency (RF) based sensing techniques to accurately measure DPF soot levels and the spatial distribution of the accumulated material. A 1.9L GM turbo diesel engine and a DPF with an RF sensor were studied. Direct comparisons between the RF measurement and conventional pressure-based methods were made. Further analysis of the particulate matter loading rates was obtained with a mass-based soot emission measurement instrument (TEOM). Comparison with pressure drop measurements show the RF technique is unaffected by exhaust flow variations and exhibits a high degree of sensitivity to DPF soot loading and good dynamic response. Additional computational and experimental work further illustrates the spatial resolution of the RF measurements. Based on the experimental results, the RF technique shows significant promise for improving DPF control, enabling optimization of the combined engine aftertreatment system for improved fuel economy and extended DPF service life.

**Modeling and Interpreting the Observed Effects of Ash on Diesel Particulate Filter Performance and Regeneration** Yujun Wang (Ph. D.), Massachusetts Institute of Technology, Department of Mechanical Engineering, 2014. Diesel particulate filters (DPF) are devices that physically capture diesel particulates to prevent their release to the atmosphere. Diesel particulate filters have seen widespread use in on and off road applications as an effective means for meeting increasingly stringent particle emissions regulations. Although the soot deposit can be removed by regeneration, the incombustible material (ash) primarily derived from metallic additives in the engine lubricant accumulates in the DPF channels with the increasing vehicle mileage or equivalent running hours. Ash accumulation inside the filter increases the flow restriction and reduces the filter soot storage capacity, which results in higher filter regeneration frequencies and larger engine fuel penalty. Combined with experimental observations, DPF models are built to investigate the fundamental mechanisms of DPF aging process. The DPF soot and ash loading model based on porous media filtration theory is applied to understand the soot deposition across the substrate wall with soot and ash cake layer formation. DPF models are also used to investigate the

process of ash transport and catalyst deactivation with increasing ash load level DPF ash aging is found to have negative effect on passive regeneration due to the catalyst deactivation and diffusion resistance of ash cake layer Besides at given amount of ash load the effects of ash spatial distribution on DPF performance are studied via simulation It is found that the ash end plug has significant influences on DPF pressure drop while ash radial and axial distributions have minor effects At known ash and substrate property DPF performance can be optimized according the sensitivity map developed from this study DPF model is beneficial to interpret the experimental observations and it is applied to predict the effects of certain factors like flow rate and deposit level on DPF performance At the same time modeling results are useful in optimizing the design of the combined engine aftertreatment lubricant system for future diesel engines and in understanding the requirements for robust aftertreatment systems

**Passive Regeneration** Michael James Bahr (Nav. E.),Massachusetts Institute of Technology. Department of Mechanical Engineering,2013 Diesel particulate filters DPF have seen widespread growth as an effective means for meeting increasingly rigorous particle emissions regulations There is growing interest to exploit passive regeneration of DPFs to reduce fuel consumption accompanying traditional active regeneration Incombustible material or ash mainly derived from metallic additives in the engine lubricant accumulates in the DPF over time This ash accumulation increases flow restriction and rise in pressure drop across the DPF The growth of pressure drop adversely impacts engine performance and fuel economy This study built upon previous research to evaluate the different effects of regeneration strategy on ash packing and distribution within DPFs Since passive regeneration relies on a catalyzed reaction the interactions of ash with the catalyst will play an important role Passive regeneration is specifically dependent on exhaust feed gas composition exhaust conditions including temperature and flow rate catalyst type and configuration and the state of DPF loading during prior to passive regeneration The goal of the study is to address the long term effects of regeneration parameters on ash accumulations and the resulting impact of ash on the DPF catalyst performance Experiments were conducted that focused on pressure drop measurements over the lifetime of diesel particulate filters with different regeneration methods coupled with post mortem ash characterization These experiments provide insight to how these regeneration methods impact the DPF performance These results among few fundamental data of this kind correlate changes in diesel particulate filter performance with exhaust conditions regeneration strategy and ash morphological characteristics Outcomes are useful in optimizing the design of the combined engine aftertreatment lubricant system for future diesel engines balancing the necessities of additives for adequate engine protection with the requirements for robust aftertreatment systems

Modeling, Estimation and Control of Integrated Diesel Engine and Aftertreatment Systems Pingen Chen,2014 The application of modern Diesel engines in automotive industry has been widely recognized for reasons of their distinguished performances on fuel economy durability and reliability Meanwhile NOx and particulate matters PM emissions have been the main concerns in the evolution of Diesel engines as more and more stringent emission standards

have been legislated against Diesel engine emissions worldwide. In addition, as the Greenhouse gas emissions are receiving more and more concerns due to global warming issues, the demand of fuel economy improvement is increasing significantly. The objective of this research is to develop systematic control methodologies based on fundamental insight into the system characteristics to improve the overall fuel economy and emission performance of integrated Diesel engine and aftertreatment systems. The test platform of this research is a medium duty Diesel engine equipped with high pressure common rail fuel injection system, dual loop exhaust gas recirculation systems, variable geometry turbocharger system and an integrated aftertreatment system including a Diesel oxidation catalyst (DOC), Diesel particulate filter (DPF) and two catalyst selective catalytic reduction (SCR) system. The topics of this research fall into two groups. The first group focuses on the modeling, estimation and control of integrated aftertreatment systems based on the interactions between the subsystems with the objective of maintaining low tailpipe emissions at low cost. Topics covered in this group include the modeling and observer based estimations for oxygen concentration and thermal behaviors across the DOC and DPF, state estimator design for SCR system using production NO<sub>x</sub> sensor measurements and the active NO/NO<sub>2</sub> ratio controller design for DOC and DPF to improve the SCR performance. The second group mainly concentrates on the modeling, estimation and control of integrated engine aftertreatment systems grounded on the interactions between engine and aftertreatment systems to simultaneously maintain high fuel efficiency and low tailpipe emissions. Topics contained in this group include the air fraction modeling and estimation for Diesel engines coupled with aftertreatment systems during normal operations and active DPF regenerations, control oriented thermal model for integrated Diesel engine and aftertreatment system, active thermal management and integrated Diesel engine and aftertreatment active NO<sub>x</sub> emissions control for fuel economy improvement. The control oriented models, observers and controllers of integrated Diesel engine and aftertreatment systems proposed in this research when applied in automotive fields have potentials of improving the engine fuel efficiency, reliability and reducing tailpipe emissions in systematic, real time and cost effective manners.

*Individual and Synergistic Effects of Lubricant Additive (Ca, Mg, Zn) Combinations on Ash Characteristics and Diesel Particulate Filters Performance* Casey Jianzhi Chiou, Massachusetts Institute of Technology, Department of Mechanical Engineering, 2013. Diesel particulate filters (DPF) are devices that trap hazardous particulate matter from diesel engine exhaust in order to meet increasingly strict particle emissions regulations. Diesel exhaust particulates mainly include soot and ash. Soot carbon particles derived from incomplete fuel combustion can be oxidized into carbon dioxide after being trapped by the DPF through a catalytic heating process called regeneration. Ash, however, derived from metallic additives in the engine lubricant required for robust engine operation is an incombustible material and remains within the DPF following regeneration. As ash accumulates over time, exhaust airflow through the filter becomes restricted and an engine backpressure results. Engine performance and fuel economy are reduced, requiring the DPF to be cleaned or replaced. While the detrimental effects of ash on DPF performance and therefore fuel economy can be

illustrated and quantified there is much to be understood about the specific factors that govern ash properties like distribution permeability and morphology Several different parameters such as engine operating conditions and DPF design have been found to significantly impact ash characteristics and the ultimate goal is to be able to control these parameters to reduce detrimental ash effects to a minimum and improve DPF service life and performance This work addresses the source of ash directly and investigates the effect of lubricant additive chemistry on ash characteristics and DPF performance Three lubricant formulations that differ only in the type of additives present are tested and compared using a controlled accelerated DPF loading system Filter pressure drop response and resulting ash property data collected using an array of experimental and analytical techniques show that very little difference exists between the tested oils of differing additive content
